Abstract

The Vapnik-Chervonenkis dimension has proven to be of great use in the theoretical study of generalization in artificial neural networks. The 'probably approximately correct' learning framework is described and the importance of the VC dimension is illustrated. We then investigate the VC dimension of certain types of linearly weighted neural networks. First, we obtain bounds on the VC dimensions of radial basis function networks with basis functions of several types. Secondly, we calculate the VC dimension of polynomial discriminant functions defined over both real and binary-valued inputs.

Contents

1 Linearly weighted neural networks

In this article we are interested in the study of two specific neural networks, taken from a very simple and extremely effective class of networks called *linearly weighted neural networks* (LWNNs). We are interested in using these networks to solve the standard two class pattern classification problem, where as usual we assume that a sequence of labelled training examples is available with which we can train a network.

A LWNN computes a function $f_{\mathbf{w}} : \mathbf{R}^n \to \{0, 1\}$ given by

$$f_{\mathbf{w}}(\mathbf{x}) = \rho[w_0 + w_1\phi_1(\mathbf{x}) + \cdots + w_m\phi_m(\mathbf{x})], \tag{1}$$

where $\mathbf{w}^T = [\ w_0 \quad w_1 \quad \cdots \quad w_m\ ]$ is a vector of weights, the *basis functions* $\phi_i : \mathbf{R}^n \to \mathbf{R}$ are arbitrary, fixed functions and the function ρ is defined as

$$\rho(x) = \begin{cases} 1 & \text{if } x \geq 0 \\ 0 & \text{otherwise.} \end{cases} \tag{2}$$

We define the class $\mathcal{F}_n^{\Phi}$ of functions computed by the network in the obvious manner as

$$\mathcal{F}_n^{\Phi} = \{f_{\mathbf{w}} \mid \mathbf{w} \in \mathbf{R}^{m+1}\} \tag{3}$$

where $\Phi = \{\phi_1, \ldots, \phi_m\}$ is the set of basis functions being used.

Networks of this general form have been studied extensively since the early 1960s; see, for example, Nilsson [23]. The general class of LWNNs described contains various popular network types as special cases, the most notable probably being the modified Kanerva model [30], regularization networks [26], and the two networks which we consider here: the radial basis function networks (RBFNs) introduced by Broomhead and Lowe [8] and the polynomial discriminant functions (PDFs) [10].

In the case of RBFNs we use a set of m basis functions of the form

$$\phi_i(\mathbf{x}) = \phi(\|\mathbf{x} - \mathbf{y}_i\|) \tag{4}$$

where $\mathbf{y}_i \in \mathbf{R}^n$ is a fixed *centre*, $\|.\|$ is the Euclidean norm and $\phi : \mathbf{R}^+ \cup \{0\} \to \mathbf{R}$ is a fixed function. These networks are discussed in detail in section 3, where we

also consider more general RBFNs. In the case of PDFs the basis functions are formed as products of elements of the input vector $\mathbf{x}$; for example,

$$\phi_i(\mathbf{x}) = x_1^2 x_2^2 x_{n-1}^5. \tag{5}$$

These networks are discussed in full in section 4.

A simple interpretation of the way in which LWNNs operate is available. Input vectors are mapped into an *extended space*[3] using the basis functions; *extended vectors* in the new space are of the form

$$\hat{\mathbf{x}}^T = [\ \phi_1(\mathbf{x}) \quad \phi_2(\mathbf{x}) \quad \cdots \quad \phi_m(\mathbf{x})\ ]. \tag{6}$$

The aim here is to produce extended vectors in such a way that the classification problem is a *linearly separable* one in the extended space, as clearly training the network by choosing a suitable $\mathbf{w}$ now corresponds to choosing a *hyperplane* (in the extended space) which correctly divides the extended vectors. Several fast training algorithms are therefore available; see for example [12].

The reader may be surprised that we consider networks of the form of equation 1 — are these networks not completely outperformed by multilayer perceptrons? The answer is in fact a definite *no*; these networks have proved to be highly successful in practice and we believe that any casual dismissal of this type of network, although quite common, is definitely misguided. We do not discuss this issue at length here: however, the reader is referred to Broomhead and Lowe [8], Niranjan and Fallside [24], Lowe [19], Renals and Rohwer [32], Kreßel *et al.* [18] and Boser *et al.* [7] for examples of the use of RBFNs, PDFs and other linearly weighted neural networks in practical applications.

2 The Vapnik-Chervonenkis dimension and the theory of generalization

In this section we introduce the VC dimension and the growth function and give a brief review of the associated computational learning theory in order to illustrate

[3] We use this term as typically $m > n$.

the importance of these parameters. A comprehensive review of the use of the VC dimension in the theory of neural networks is given in Holden [16].

A given neural network computes a class $\mathcal{F}$ of functions $f_{\mathbf{w}} : \mathbf{R}^n \to \{0,1\}$, the actual function computed depending on the specific weight vector used.

Definition 1 *We define the* hypothesis $h_{\mathbf{w}}$ *associated with a function* $f_{\mathbf{w}}$ *as the subset of* $\mathbf{R}^n$ *for which* $f_{\mathbf{w}}(\mathbf{x}) = 1$,

$$h_{\mathbf{w}} = \{\mathbf{x} \in \mathbf{R}^n \mid f_{\mathbf{w}}(\mathbf{x}) = 1\}. \tag{7}$$

The hypothesis space H *computed by the network is the set*

$$H = \{h_{\mathbf{w}} \mid \mathbf{w} \in \mathbf{R}^W\} \tag{8}$$

of all hypotheses where W *is the total number of weights used by the network.*

2.1 The VC dimension

The VC dimension can be regarded as a measure of the 'capacity' of a network, or of the 'expressive power' of its hypothesis space. It was introduced, along with the growth function by Vapnik and Chervonenkis [36] in their study of the uniform convergence of relative frequencies to probabilities and has recently become important in machine learning. The reasons for its importance in this field are introduced below.

Definition 2 *Given a set* $S \subseteq \mathbf{R}^n$ *and some function* $f_{\mathbf{w}} \in \mathcal{F}$ *we define the* dichotomy (S^+, S^-) of S induced by $f_{\mathbf{w}}$ *to be the partition of* S *into the disjoint subsets* S^+ *and* S^- *where* $S^+ \cup S^- = S$ *and* $\mathbf{x} \in S^+$ *if* $f_{\mathbf{w}}(\mathbf{x}) = 1$, $\mathbf{x} \in S^-$ *if* $f_{\mathbf{w}}(\mathbf{x}) = 0$.

Definition 3 *Given a hypothesis space* H *and* $S \in \mathbf{R}^n$ *we define* $\triangle_H(S)$ *as the set*

$$\triangle_H(S) = \{h \cap S \mid h \in H\}. \tag{9}$$

We say that S *is* shattered *by* H *if* $\triangle_H(S) = 2^S$ *where* 2^S *is the set of all subsets of* S.

The growth function and the VC dimension are now defined as follows.

Definition 4 (Growth Function) *The growth function is defined on the set of positive integers as*

$$\triangle_H(i) = \max_{S \subseteq \mathbf{R}^n, |S|=i} (| \triangle_H(S) |). \tag{10}$$

Definition 5 (Vapnik-Chervonenkis dimension) *The VC dimension $\mathcal{V}(H)$ of a hypothesis space H is the largest integer i such that $\triangle_H(i) = 2^i$, or infinity if no such i exists.*

The growth function thus tells us the maximum number of different dichotomies induced by $\mathcal{F}$ for any set of i points, and the VC dimension tells us the size of the largest set of points shattered by H. Note that due to the close relationship between H, $\mathcal{F}$ and the actual neural network with which we are dealing, we can refer to the growth function and the VC dimension of $\mathcal{F}$ and of the neural network and can define the quantities $\triangle_{\mathcal{F}}(S_k)$, $\triangle_{\mathcal{F}}(i)$ and $\mathcal{V}(\mathcal{F})$ in the obvious manner.

Example 1: Consider the class of functions of the form

$$\mathcal{F} = \{f_{\mathbf{w}}(\mathbf{x}) = \rho[w_0 + w_1 x_1 + \cdots + w_n x_n] \mid \mathbf{w} \in \mathbf{R}^{n+1}\} \tag{11}$$

which is the class of *linear threshold functions* (LTFs). It is well known that $\mathcal{V}(\mathcal{F}) = n+1$ (see for example Wenocur and Dudley [38]). When $w_0 = 0$ we have the class of *homogeneous LTFs* and $\mathcal{V}(\mathcal{F}) = n$. □

Example 2: As a more interesting example, consider the class of feedforward networks of LTFs having W weights and N computation nodes. A full definition of this type of network is given in [4]; it corresponds to the standard multilayer perceptron network. It is proved in [4] that for the class $\mathcal{F}_{W,N}$ of functions computed by any one of these networks,

$$\mathcal{V}(\mathcal{F}_{W,N}) \leq 2W \log_2(eN). \tag{12}$$

The best lower bound on the VC dimension of networks of this general type is $\Omega(W \log_2 W)$, as proved by Maass [20]. This implies that the bound of equation 12

is asymptotically optimal. Various other bounds on the VC dimension for specific networks in this class can be found in Bartlett [5]. □

Example 3: Consider again the definition of $\mathcal{F}_n^\Phi$, the class of functions computed by the networks we will consider, given in equation 3. In Holden and Rayner [17] it was shown that

$$\mathcal{V}(\mathcal{F}_n^\Phi) \leq m + 1 \tag{13}$$

regardless of the functions actually included in Φ. It is the purpose of this article to argue that in practice we can, in many of the cases normally considered, expect to obtain $\mathcal{V}(\mathcal{F}_n^\Phi) \simeq m + 1$. We remark that if the set of functions $\{1, \phi_1, \ldots, \phi_m\}$ is linearly independent then equality holds in equation 13; this is a direct consequence of a theorem of Dudley [13] (see section 4). Also, it is easy to see that if we construct a network which does not include the term w_0 then $\mathcal{V}(\mathcal{F}_n^\Phi) \leq m$. □

There is a well-known result, commonly known as *Sauer's lemma*, which, given the VC dimension of some class $\mathcal{F}$ of functions, provides an upper bound on the growth function.

Lemma 6 (Sauer [33], Blumer *et al.* **[6])** *Given a class $\mathcal{F}$ of functions for which $\mathcal{V}(\mathcal{F}) = d \geq 0$ and $d < \infty$,*

$$\triangle_{\mathcal{F}}(k) \leq \Psi(d, k) = 1 + \sum_{i=1}^{d} \binom{k}{i}, \tag{14}$$

where $k \geq 1$. When $k \geq d \geq 1$,

$$\Psi(d, k) < \left(\frac{ek}{d}\right)^d. \tag{15}$$

For finite $\mathcal{V}(\mathcal{F})$ a further useful bound, from [36], is

$$\triangle_{\mathcal{F}}(k) \leq k^{\mathcal{V}(\mathcal{F})} + 1. \tag{16}$$

Clearly if $\mathcal{V}(\mathcal{F}) = \infty$ then $\triangle_{\mathcal{F}}(k) = 2^k$ for all k.

2.2 Using the growth function and the VC dimension to analyse generalization

Consider a neural network which computes a class $\mathcal{F}$ of functions. We can regard the process of training this network as a process of trying to find some $f_{\mathbf{w}} \in \mathcal{F}$ which is a 'good approximation' to some target function f_T on a given set of training examples. Let $\mathbf{x} \in \mathbf{R}^n$ be chosen at random according to some arbitrary probability distribution P on $\mathbf{R}^n$. We define $\pi_{f_{\mathbf{w}}}$ to be the probability that $f_{\mathbf{w}}$ agrees with the target function on an example chosen at random according to the distribution P; that is,

$$\pi_{f_{\mathbf{w}}} = \Pr\left[f_{\mathbf{w}}(\mathbf{x}) = f_T(\mathbf{x})\right]. \tag{17}$$

Let $T_k = ((\mathbf{x}_1, f_T(\mathbf{x}_1)), \ldots, (\mathbf{x}_k, f_T(\mathbf{x}_k)))$ be a sequence of k training examples where the inputs $\mathbf{x}_i$ are picked independently according to P and define $v_{f_{\mathbf{w}}}$ to be the fraction of the inputs in T_k which are classified correctly by $f_{\mathbf{w}}$. When we train a neural network we choose a particular vector of weights $\mathbf{w}$ on the basis of the value of $v_{f_{\mathbf{w}}}$, and we thus need to know whether $v_{f_{\mathbf{w}}}$ converges to $\pi_{f_{\mathbf{w}}}$ in a uniform way for all $f_{\mathbf{w}} \in \mathcal{F}$ as k becomes large. If this is not the case then we may end up choosing a function $f_{\mathbf{w}}$ for which the value of $\pi_{f_{\mathbf{w}}}$ is in fact relatively low. An inequality derived in [35] yields a bound on the probability that there is a function $f_{\mathbf{w}} \in \mathcal{F}$ for which $\pi_{f_{\mathbf{w}}}$ and $v_{f_{\mathbf{w}}}$ differ significantly. Specifically, given a particular value of α,

$$\Pr\left[\sup_{f_{\mathbf{w}} \in \mathcal{F}} \frac{v_{f_{\mathbf{w}}} - \pi_{f_{\mathbf{w}}}}{\sqrt{1 - \pi_{f_{\mathbf{w}}}}} > \alpha\right] \leq 4 \triangle_{\mathcal{F}}(2k) \exp\left(\frac{-\alpha^2 k}{4}\right). \tag{18}$$

(The result quoted here is based on a slight improvement on the original result of Vapnik; see Anthony and Shawe-Taylor [3].) Now, by equation 16 if $\mathcal{V}(\mathcal{F})$ is finite then $\triangle_{\mathcal{F}}(k)$ is bounded above by a polynomial function of k and thus, since $\exp\left(\frac{-\alpha^2 k}{4}\right)$ decays exponentially in k, we can make the right-hand side of equation 18, and hence the generalization error, arbitrarily small by choosing k large enough. Further, equation 18 provides a bound on the rate of convergence which is independent of the particular probability distribution P and the particular target function f_T. The VC dimension clearly influences the speed of convergence and consequently the number of examples required to guarantee a particular generalization performance.

2.3 VC dimension and computational learning theory

The above discussion illustrates one reason for the importance of the VC dimension and growth function in the analysis of generalization in neural networks and other systems. In their analysis of valid generalization in general feedforward networks of LTFs, Baum and Haussler [4] used a modified form of *Probably Approximately Correct (PAC) learning theory*, introduced by Blumer *et al.* [6] and based on the work of Valiant [34], to relate network size to generalization ability. This work has recently been extended to a class of networks described in section 1 by Holden and Rayner [17], to networks with more than one output node by Anthony and Shawe-Taylor [3], and to networks with real-valued outputs by Haussler [15] . In this section we give a brief introduction to the formalism.

2.3.1 Standard PAC learning

Consider a neural network having a hypothesis space H. We define a *concept class* C in a similar manner as a set of subsets of $\mathbf{R}^n$. In general we also impose some further restrictions on C and H, details of which can be found in [6]; these are rather technical and do not introduce problems for the neural networks likely to be used in practice. The concept class C may or may not be equal to the hypothesis space H. Now, given a target concept $c_T \in C$, training corresponds to choosing a weight vector $\mathbf{w}$ such that the hypothesis $h_{\mathbf{w}}$ is a good approximation to c_T.

Once again we have a sequence $T_k = ((\mathbf{x}_1, o_1), \ldots, (\mathbf{x}_k, o_k))$ of k training examples where the inputs $\mathbf{x}_i$ are drawn independently from an arbitrary distribution P on $\mathbf{R}^n$ and o_i is equal to 1 if $\mathbf{x}_i \in c_T$ and 0 otherwise. We define a *learning function* for C as a function which given a T_k for large enough k and any $c_T \in C$ will return a hypothesis $h_{\mathbf{w}} \in H$ which is, with high probability, a good approximation to c_T. Formally, the *error* of a hypothesis $h_{\mathbf{w}}$ is the probability according to P of the symmetric difference $h_{\mathbf{w}} \triangle c_T$. Given small, specified ϵ and δ, we demand that there is some k, which does not depend on either the probability distribution P or on c_T, such that the hypothesis $h_{\mathbf{w}}$ produced by the learning function satisfies

$$\Pr[h_{\mathbf{w}} \triangle c_T > \epsilon] \leq \delta. \tag{19}$$

It is worth emphasising again that we require there to be a suitable k which depends *only* on ϵ and δ. The *sample complexity* of the learning function is the smallest value of k guaranteed to achieve this, and any concept class for which there is such a learning function is said to be *uniformly learnable*.

An important result proved in [6] is that C is uniformly learnable if and only if $\mathcal{V}(C)$ is finite. An account of PAC learning theory can be found in [2].

2.3.2 Extended PAC learning

Some shortcomings of PAC learning as described above should immediately be apparent. In this formalism there is no satisfactory way in which to deal with a sequence T_k containing misclassifications. There is also no way in which to deal with a target concept which has been defined in a stochastic manner — a common assumption in pattern recognition — rather than a deterministic concept c_T.

PAC learning is extended in [6] in such a way that T_k is generated by drawing examples independently from an arbitrary distribution P' on $\mathbf{R}^n \times \{0,1\}$. The error with respect to P' of a function $f_{\mathbf{w}}$ computed by a neural network is then defined as

$$\Pr[f_{\mathbf{w}}(\mathbf{x}) \neq o] \tag{20}$$

where $(\mathbf{x}, o)$ is a random example. Note that now we cannot in general even define a deterministic target concept, as given some $\mathbf{x} \in \mathbf{R}^n$ both $(\mathbf{x}, 1)$ and $(\mathbf{x}, 0)$ may have non-zero probability. We are now able to model the situation in which examples in T_k are generated as in the standard PAC learning model but where $\mathbf{x}_i$ or o_i are subsequently modified by some random process.

In a similar manner to that described above, this extended PAC learning formalism requires us to search for a hypothesis $h_{\mathbf{w}} \in H$ which, with high probability, is a good approximation to a particular stochastic target concept. In order to illustrate the importance of the growth function and the VC dimension in the theory we state the following theorem, which follows from the same general result of Vapnik as does equation 18. Some measurability conditions on the class $\mathcal{F}$ of functions computed by the network must be satisfied; see Blumer *et al.* [6]

and Pollard [27] for details; these are once again never a cause for concern in practice. For applications of this theorem see Baum and Haussler [4] and Holden and Rayner [17].

Theorem 7 (Vapnik [35], Blumer *et al.* **[6])** *Consider the class $\mathcal{F}$ of functions $f_{\mathbf{w}} : \mathbf{R}^n \to \{0,1\}$ and a sequence T_k of examples as described above. Let γ, δ and ϵ be such that $0 < \gamma \leq 1$, $\delta < 1$ and $\epsilon > 0$ and define $\mathcal{P}$ as the probability that there exists some function $f_{\mathbf{w}} \in \mathcal{F}$ which disagrees with at most a fraction $(1-\gamma)\epsilon$ of the examples in T_k but has an error which is greater than ϵ. Then $\mathcal{P}$ satisfies*

$$\mathcal{P} < 4 \triangle_{\mathcal{F}}(2k) \exp\left(\frac{-\gamma^2 \epsilon k}{4}\right). \tag{21}$$

This theorem is important because, clearly, if we can find an upper bound on the growth function of the network, for example by finding its VC dimension and applying Sauer's lemma, then we can say something about its ability to generalize. Specifically, if our network can be trained to classify correctly a fraction $1-(1-\gamma)\epsilon$ of the k training examples, the probability that its error — a measure of its ability to generalize — is less than ϵ is at least $1-\mathcal{P}$. This is exactly the type of analysis carried out in [4, 17], and as the growth function and VC dimension tend to depend quite specifically on the *size* of the network measured in terms of, for example, the total number of parameters adapted during training, this type of analysis generally allows us to relate the size of a network to the number of examples which must be learnt in order to obtain valid generalization.

3 Radial basis function networks

Radial basis function networks in their most general form compute functions $f_{\mathbf{w}} : \mathbf{R}^n \to \{0,1\}$ where,

$$f_{\mathbf{w}} = \rho[\overline{f}_{\mathbf{w}}(\mathbf{x})]. \tag{22}$$

The function $\overline{f}_{\mathbf{w}} : \mathbf{R}^n \to \mathbf{R}$ is of the form,

$$\overline{f}_{\mathbf{w}}(\mathbf{x}) = \sum_{i=1}^{p} \lambda_i \phi(\|\mathbf{x} - \mathbf{y}_i\|) + \sum_{i=1}^{q} \theta_i \psi_i(\mathbf{x}) \text{ where } q \leq p \tag{23}$$

in which $\mathbf{w}^T = [\ \lambda_1 \quad \lambda_2 \quad \cdots \quad \lambda_p \quad \theta_1 \quad \theta_2 \quad \cdots \quad \theta_q\ ]$ is a vector of weights, $\mathbf{y}_i \in \mathbf{R}^n$ are *centres* of the basis functions, $\phi : \mathbf{R}^+ \cup \{0\} \rightarrow \mathbf{R}$, $\|.\|$ is the Euclidean norm, and $\{\psi_i \mid i = 1, \ldots, q\}$ is a basis of the vector space $\pi_{d-1}(\mathbf{R}^n)$ of algebraic polynomials from $\mathbf{R}^n$ to $\mathbf{R}$ of degree at most $(d-1)$ for some specified d.

Networks of this type were originally introduced by Broomhead and Lowe [8], whose work should be consulted for further details. Their main motivation was that, as we shall see below, the networks have a sound theoretical basis in interpolation theory. The networks can also be regarded as a special case of the regularization networks introduced by Poggio and Girosi [26] and thus have a theoretical justification in terms of standard regularization theory. Networks of this general type have been shown to perform well in comparison to many available alternatives — see, for example, Niranjan and Fallside [24] — and training algorithms are available which are considerably faster than hidden layer back-propagation; see for example Moody and Darken [22] and Chen *et al.* [9].

It is usual in practice not to include the polynomial terms in the network, so that the network computes functions,

$$f_{\mathbf{w}}(\mathbf{x}) = \rho \left[\sum_{i=1}^{p} \lambda_i \phi(\|\mathbf{x} - \mathbf{y}_i\|) \right]. \tag{24}$$

A single constant offset term λ_0 is often added to the summation, but is omitted here.

In this section we investigate the VC dimension of this class of networks, using various standard choices for the basis function ϕ. We will mostly be interested in networks where the centres $\mathbf{y}_i$ are fixed, although we briefly mention networks with variable centres in section 3.3. Our proof technique is a simple one relying on the interpolation properties of the functions $\overline{f}_{\mathbf{w}}$, and in particular on the use of two well known theorems due to Micchelli [21].

3.1 Interpolation and Micchelli's theorems

Why use functions of the form of equation 22? Broomhead and Lowe [8] introduced RBFNs on the basis that functions of the form of $\overline{f}_{\mathbf{w}}$ had previously

proved very useful in the theory of multivariable interpolation (a review is given by Powell [28, 29]; see also [26] on which our review is based).

Consider the problem of finding a function $g : \mathbf{R}^n \to \mathbf{R}$ which is a member of a given class of functions $\mathcal{G}$ and which exactly interpolates a set T_k of k examples,

$$T_k = \{(\mathbf{x}_1, o_1), \ldots, (\mathbf{x}_k, o_k)\} \tag{25}$$

where $\mathbf{x}_i \in \mathbf{R}^n$ are distinct vectors and $o_i \in \mathbf{R}$ can be chosen arbitrarily. This means that g must satisfy

$$g(\mathbf{x}_i) = o_i \text{ for } i = 1, \ldots, k. \tag{26}$$

Now let $\mathcal{G}'$ denote the class of functions $\mathcal{G}' = \{\rho \circ g \mid g \in \mathcal{G}\}$ where $\circ$ denotes function composition. Assume we have a *particular* set $S_k = \{\mathbf{x}_1, \ldots, \mathbf{x}_k\}$ of k points where $\mathbf{x}_i \in \mathbf{R}^n$, and we form a corresponding set T_k having arbitrary o_i. Now clearly if we can prove that given such a set T_k there exists, regardless of the o_i used, a $g \in \mathcal{G}$ which performs the interpolation, then $\mathcal{V}(\mathcal{G}') \geq k$. This is because, given any particular dichotomy (S_k^+, S_k^-) of the initial set S_k, we simply pick o_i to be an arbitrary positive quantity when $\mathbf{x}_i \in S_k^+$ and an arbitrary negative quantity when $\mathbf{x}_i \in S_k^-$. As there is a $g \in \mathcal{G}$ which interpolates the corresponding T_k, the corresponding $g' = \rho \circ g$ induces the required dichotomy, and as this applies to *any* dichotomy, $\mathcal{G}'$ shatters S_k.

The functions $\overline{f}_{\mathbf{w}}$ are useful because it is always possible to interpolate k points in such a set S_k using a function

$$\overline{f}_{\mathbf{w}}(\mathbf{x}) = \sum_{i=1}^{k} \lambda_i \phi(\|\mathbf{x} - \mathbf{x}_i\|) + \sum_{i=1}^{q} \theta_i \psi_i(\mathbf{x}), \text{ where } q \leq k, \tag{27}$$

regardless of the values chosen for o_i, provided ϕ satisfies some simple conditions which we discuss below. The class of functions $\mathcal{G}$ is now simply

$$\mathcal{G} = \{\overline{f}_{\mathbf{w}} \mid \mathbf{w} \in \mathbf{R}^{k+q}\}, \tag{28}$$

where $\overline{f}_{\mathbf{w}}$ is as defined in equation 27. Notice that in equation 27 the original centres $\mathbf{y}_i$ of $\overline{f}_{\mathbf{w}}$ have been made to correspond to the points $\mathbf{x}_i$. Notice also that when using functions $\overline{f}_{\mathbf{w}}$ in this manner the constraints of equation 26 give us a

set of k linear equations for $(k+q)$ coefficients. The remaining degrees of freedom are fixed by requiring that,

$$\sum_{i=1}^{k} \lambda_i \psi_j(\mathbf{x}_i) = 0 \text{ where } j = 1, \ldots, q. \tag{29}$$

A sufficient condition on ϕ for the existence of an interpolating function of the form of equation 27 is that $\phi \in \mathbf{P}_d(\mathbf{R}^n)$ where $\mathbf{P}_d(\mathbf{R}^n)$ is the set of *strictly conditionally positive definite (SCPD) functions of order d.*

Definition 8 *Suppose h is a continuous function on $[0, \infty)$. This function is strictly conditionally positive definite of order $d \geq 1$ on $\mathbf{R}^n$ if for any k distinct points $\mathbf{x}_1, \ldots, \mathbf{x}_k$ in $\mathbf{R}^n$ and $c_1, \ldots, c_k \in \mathbf{R}$ (not all 0) where*

$$\sum_{i=1}^{k} c_i \psi(\mathbf{x}_i) = 0 \tag{30}$$

for all $\psi \in \pi_{d-1}(\mathbf{R}^n)$, the quadratic form $\sum_{i=1}^{k} \sum_{j=1}^{k} c_i c_j h(\|\mathbf{x}_i - \mathbf{x}_j\|)$ is positive. The function is SCPD of order 0 if the form $\sum_{i=1}^{k} \sum_{j=1}^{k} c_i c_j h(\|\mathbf{x}_i - \mathbf{x}_j\|)$ is positive definite.

Let $\mathbf{P}_d$ be the set of functions which are in $\mathbf{P}_d(\mathbf{R}^n)$ over any $\mathbf{R}^n$,

$$\mathbf{P}_d = \bigcap_{n \geq 1} \mathbf{P}_d(\mathbf{R}^n). \tag{31}$$

Note that for all non-negative integers d, $\mathbf{P}_d \subseteq \mathbf{P}_{d+1}$. An important theorem due to Micchelli provides us with a simple means of determining whether a function ϕ is in $\mathbf{P}_d$, and hence whether it is a suitable basis function for use in forming $\overline{f}_{\mathbf{w}}$. We first need to define a *completely monotonic* function.

Definition 9 *A function h is* completely monotonic *on $(0, \infty)$ if $h \in C^{\infty}(0, \infty)$ and its sequence of derivatives is such that*

$$(-1)^i h^{(i)}(x) \geq 0 \tag{32}$$

for $x \in (0, \infty)$ and $i = 0, 1, 2, \ldots$.

Theorem 10 (Micchelli [21], Dyn and Micchelli [14]) *If a function $h(r)$ is continuous on $[0,\infty)$, $h(r^2) \in C^\infty(0,\infty) \cap C[0,\infty)$ and $(-1)^d h^{(d)}$ is completely monotonic on $(0,\infty)$ but not constant then $h(r^2)$ is in $\mathbf{P}_d$.*

Now, consider the special case in which we attempt to interpolate the data in T_k using

$$\overline{f}_{\mathbf{w}}(\mathbf{x}) = \sum_{i=1}^{k} \lambda_i \phi(\|\mathbf{x} - \mathbf{x}_i\|). \tag{33}$$

The function $\rho \circ \overline{f}_{\mathbf{w}}$ now corresponds to the networks most often used in practice. The interpolation is possible provided we can find a solution to the set of equations

$$\mathbf{o} = \begin{bmatrix} o_1 \\ o_2 \\ \vdots \\ o_k \end{bmatrix} = \begin{bmatrix} \phi_{11} & \phi_{12} & \cdots & \phi_{1k} \\ \phi_{21} & \phi_{22} & \cdots & \phi_{2k} \\ \vdots & \vdots & \ddots & \vdots \\ \phi_{k1} & \phi_{k2} & \cdots & \phi_{kk} \end{bmatrix} \begin{bmatrix} \lambda_1 \\ \lambda_2 \\ \vdots \\ \lambda_k \end{bmatrix} = \boldsymbol{\phi}\boldsymbol{\lambda} \tag{34}$$

where $\phi_{ij} = \phi(\|\mathbf{x}_i - \mathbf{x}_j\|)$, so that

$$\boldsymbol{\lambda} = \boldsymbol{\phi}^{-1}\mathbf{o}. \tag{35}$$

It is possible to show (see Powell [29]) that $\boldsymbol{\phi}$ is nonsingular if ϕ is SCPD of order 0, or if ϕ is SCPD of order 1 and $\phi(0) \leq 0$. Thus, in some cases theorem 10 will tell us whether a particular ϕ can be used successfully. An alternative sufficient condition also exists for this special case, again proved by Micchelli.

Theorem 11 (Micchelli [21]) *If h is continuous on $[0,\infty)$, positive on $(0,\infty)$, and has a first derivative that is completely monotonic but not constant on $(0,\infty)$, then for any set of k vectors $\mathbf{x}_i \in \mathbf{R}^n$ where n is arbitrary,*

$$(-1)^{k-1}\det h(\|\mathbf{x}_i - \mathbf{x}_j\|^2) > 0. \tag{36}$$

Now clearly if we choose a suitable function ϕ such that $\phi(\sqrt{r})$ satisfies the conditions in theorem 11 it is not possible that $\det(\boldsymbol{\phi}) = 0$, which implies that $\boldsymbol{\phi}$ must be nonsingular and consequently that there exists a suitable weight vector $\boldsymbol{\lambda}$ regardless of the actual values for o_i used.

Form of basis function	Type of basis function
$\phi_{LIN}(r) = r$	Linear
$\phi_{CUB}(r) = r^3$	Cubic
$\phi_{TPS}(r) = r^2 \ln r$	Thin plate spline
$\phi_{MQ}(r) = (r^2 + c^2)^{\frac{1}{2}}, c \in \mathbf{R}^+$	Multiquadric
$\phi_{IMQ}(r) = (r^2 + c^2)^{-\frac{1}{2}}, c \in \mathbf{R}^+$	Inverse Multiquadric
$\phi_{GAUSS}(r) = \exp\left[-\left(\frac{r}{c}\right)^2\right], c \in \mathbf{R}^+$	Gaussian

Table 1: Standard basis functions used in radial basis function networks.

In summary, provided we use a basis function ϕ chosen using the relevant conditions given in theorem 10 or theorem 11, then our radial basis function network, having fixed centres and as defined in equation 22 shatters the set of p vectors $\{\mathbf{x}_i\}$ which correspond to the centres $\{\mathbf{y}_i\}$ such that

$$\mathbf{x}_i = \mathbf{y}_i \text{ where } i = 1, \ldots, p. \tag{37}$$

3.2 Networks with fixed centres

Table 1 summarizes some of the usual basis functions ϕ used in RBFNs; two further standard basis functions are given in equation 39 below. The use of these functions is justified by the theory introduced above [26]. Note that the parameter c is fixed — it is not adapted during training. We immediately obtain the following two corollaries.

Corollary 12 *Consider the simple RBFNs of the form,*

$$f_{\mathbf{w}}(\mathbf{x}) = \rho\left[\sum_{i=1}^{p} \lambda_i \phi(\|\mathbf{x} - \mathbf{y}_i\|)\right] \tag{38}$$

where the centres $\mathbf{y}_i$ are fixed and distinct. If ϕ is one of the functions ϕ_{LIN}, ϕ_{GAUSS}, ϕ_{MQ} or ϕ_{IMQ} then the VC dimension $\mathcal{V}(\mathcal{F})$ of the network is exactly p. This result also applies if ϕ is one of the following two functions, which are more

general forms of the multiquadric and inverse multiquadric respectively.

$$\begin{aligned} \phi^*_{MQ}(r) &= (r^2 + c^2)^\beta \text{ where } 0 < \beta < 1 \\ \phi^*_{IMQ}(r) &= (r^2 + c^2)^{-\alpha} \text{ where } \alpha > 0. \end{aligned} \tag{39}$$

Clearly ϕ_{MQ} and ϕ_{IMQ} are special cases of ϕ^*_{MQ} and ϕ^*_{IMQ} respectively.

Proof: The functions ϕ_{GAUSS} and ϕ^*_{IMQ} are in $\mathbf{P}_0$ by theorem 10 and the functions $\sqrt{r}$ and $(r+c^2)^\beta$ where $0 < \beta < 1$ satisfy the conditions in theorem 11. This means that by the arguments given above $\mathcal{V}(\mathcal{F}) \geq p$ for all four cases. Also, from example 3 we know that $\mathcal{V}(\mathcal{F}) \leq p$, and consequently we must have $\mathcal{V}(\mathcal{F}) = p$. □

Corollary 13 *Consider the RBFNs of the form,*

$$f_{\mathbf{w}}(\mathbf{x}) = \rho \left[\sum_{i=1}^{p} \lambda_i \phi(\|\mathbf{x} - \mathbf{y}_i\|) + \psi(\boldsymbol{\theta}, \mathbf{x}) \right] \tag{40}$$

where $\psi(\boldsymbol{\theta}, \mathbf{x})$ is the degree 1 polynomial,

$$\psi(\boldsymbol{\theta}, \mathbf{x}) = \theta_0 + \theta_1 x_1 + \theta_2 x_2 + \cdots + \theta_n x_n, \tag{41}$$

x_i are the elements of $\mathbf{x}$, and $p \geq n+1$. Again, the centres $\mathbf{y}_i$ are fixed and distinct. If ϕ is the function ϕ_{CUB} or ϕ_{TPS} then the VC dimension of the network obeys $p \leq \mathcal{V}(\mathcal{F}) \leq p + n + 1$.

Proof: By theorem 10 both ϕ_{CUB} and ϕ_{TPS} are in $\mathbf{P}_2$ and hence $\mathcal{V}(\mathcal{F}) \geq p$. From example 3 we know that $\mathcal{V}(\mathcal{F}) \leq p + n + 1$ and the results follows. □

3.3 Networks with variable centres

What happens to the VC dimension of a radial basis function network if we allow its centres $\mathbf{y}_i$ to adapt during training, rather than force them to remain fixed? Obviously, the results presented above provide lower bounds on the VC dimension of RBFNs having basis functions ϕ of the appropriate type. We also have the following simple result.

Corollary 14 *Consider the networks of the types mentioned in corollaries 12 and 13. If the centres* $\mathbf{y}_i$ *are allowed to adapt then the networks can all form* arbitrary *dichotomies of* any *set of* p *distinct points.*

The proof of this result is trivial — the networks can shatter the set of p points corresponding to the p centres $\mathbf{y}_i$ and these centres can now be placed anywhere. It is interesting that there is no requirement that the p points be in any kind of *general position* as is often the case in similar results for other types of network (see Cover [10]).

Corollary 14 suggests that the lower bounds suggested for the VC dimension of this type of network are unlikely to be tight. We have not been able to improve them however, and we leave as an open question whether or not it is possible to obtain a lower bound similar to that recently proved by Maass [20] for certain feedforward networks, and mentioned in example 2. Similarly, we have not been able to prove upper bounds on the VC dimension of these networks for all but the simplest cases. For example, if ϕ is a function,

$$\phi(r) = r^i \text{ where } i \text{ is even} \tag{42}$$

then the network computes a class of polynomial discriminant functions and the results of section 4 can be applied.

4 Polynomial discriminant functions

In this section, we discuss the polynomial discriminant functions (PDFs), determining the VC dimension in two distinct situations: when the inputs are real numbers and when the inputs are restricted to be binary-valued (that is, 0 or 1). As mentioned in Section 1, the PDFs are linearly weighted neural networks in which the basis functions compute some of the products of the entries of the input vectors. In other words,

$$\tilde{\mathbf{x}}^T = [\ \phi_1(\mathbf{x}) \quad \phi_2(\mathbf{x}) \quad \cdots \quad \phi_m(\mathbf{x})\ ], \tag{43}$$

where each ϕ_i is of the form

$$\phi_i(\mathbf{x}) = \prod_{1 \leq i \leq n} x_i^{r_i}, \tag{44}$$

for some non-negative integers r_i. We say that the PDF is of *order at most* k when the largest degree of any of the multinomial basis functions ϕ_i used to define f is k; that is, if f can be expressed as a LWNN over those basis functions in equation 44 having $\sum_{i=1}^{n} r_i \leq k$. Furthermore, the order of a PDF f is said to be precisely k when f has order at most k but not at most $k-1$; that is, when in every representation of f in the form given in equation 1, one of the basis functions required has degree k. Thus the PDFs of order 1 are precisely the linear threshold functions of Example 1 and, for example, the PDFs of order 2 defined on $\mathbf{R}^3$ are of the form

$$\rho[w_0 + w_1x_1 + w_2x_2 + w_3x_3 + w_4x_1^2 + w_5x_2^2 + w_6x_3^2 + w_7x_1x_2 + w_8x_1x_3 + w_9x_2x_3] \tag{45}$$

for some contants w_i, $(0 \leq i \leq 9)$, in which at least one of the terms of degree 2 has a non-zero coefficient.

Polynomial discriminators have been studied in the the context of pattern classification (see, for example, [12, 11, 23]), where the aim is to classify a given set of test data points into two categories correctly, this classification being used as a (hopefully valid) means of classifying further points. In addition, they have recently been employed in signal processing [31]. It is therefore an important problem to determine the 'power' of classification achievable by such discriminators and to quantify the sample size required for valid learning.

We shall denote by $\mathcal{P}(n,k)$ the (full) class of PDFs of order at most k defined on $\mathbf{R}^n$. That is, $\mathcal{P}(n,k)$ is the set of linearly weighted neural networks formed from all basis functions of degree at most k of the form ϕ_i given in equation 44. Further, we shall denote by $\mathcal{P}_{\mathbf{B}}(n,k)$ the (full) class of *boolean PDFs* obtained by restricting $\mathcal{P}(n,k)$ to binary-valued inputs; i.e., to $\{0,1\}^n$. Thus $\mathcal{P}(n,k)$ is the set of $\{0,1\}$ functions on $\mathbf{R}^n$ whose positive and negative examples are separated by some surface which can be described by a multinomial equation of degree at most k and $\mathcal{P}_{\mathbf{B}}(n,k)$ is the set of $\{0,1\}$ functions on $\{0,1\}^n$ (i.e, Boolean functions of n variables) whose positive and negative examples can be separated in this way. To start with, we consider only these two classes of PDFs. Later we shall discuss

more restricted classes; for example, one may be interested only in PDFs over a restricted set of all basis functions ϕ_i of at most a given degree.

4.1 Threshold order of a boolean function

As an example, consider the exclusive-or boolean function XOR of two variables, defined by

$$\mathrm{XOR}((x_1, x_2)) = \begin{cases} 1 & \text{if } x_1 \neq x_2 \\ 0 & \text{if } x_1 = x_2. \end{cases} \tag{46}$$

Clearly the exclusive-or function is not a linear threshold boolean function; that is, it does not lie in $\mathcal{P}_{\mathbf{B}}(2,1)$. However, it does lie in $\mathcal{P}_{\mathbf{B}}(2,2)$. One representation of XOR in $\mathcal{P}_{\mathbf{B}}(2,2)$ is

$$\mathrm{XOR}((x_1, x_2)) = \rho[x_1 + x_2 - 4x_1x_2 - 1]. \tag{47}$$

One way in which to quantify the power of binary-input polynomial discriminant functions of a given degree is to bound the number of functions realised by such discriminators. Wang and Williams [37] have studied the classes $\mathcal{P}_{\mathbf{B}}(n,k)$ and have shown that every boolean function is in $\mathcal{P}_{\mathbf{B}}(n,k)$ for some $k \leq n$. In particular, the *parity* function on n variables is in $\mathcal{P}_{\mathbf{B}}(n,n)$ but not in $\mathcal{P}_{\mathbf{B}}(n,n-1)$. (Note that XOR is the parity function of 2 variables.) Since each boolean function of n variables lies in $\mathcal{P}_{\mathbf{B}}(n,n)$, it is possible, as in [37], to define the *threshold order* of a boolean function f to be the least value of k for which $f \in \mathcal{P}_{\mathbf{B}}(n,k)$. Wang and Williams asked for bounds on the cardinalities of the sets $\mathcal{P}_{\mathbf{B}}(n,k)$ and made a number of conjectures. In particular, they conjectured, as Anthony [1] has recently shown, that for large n, all but a negligible proportion of the boolean functions of n variables have threshold order at least $\lfloor n/2 \rfloor$ and that for odd values of n, at most half have threshold order equal to $\lfloor n/2 \rfloor$. This shows, in a sense, that the PDFs are of limited expressive power; however, it is certainly very demanding to require that a class of boolean functions compute most boolean functions and it is, for the reasons discussed in section 2, more appropriate in learning theory to quantify expressive power through the VC dimension. First, though, we introduce some notations.

4.2 Further notations and definitions

Let us denote the set $\{1, 2, \ldots, n\}$ by $[n]$. We shall denote the set of all subsets of at most k objects from $[n]$ by $[n]^{(k)}$ and we shall denote by $[n]^k$ the set of all selections, in which repetition is allowed, of at most k objects from $[n]$. Thus, $[n]^k$ may be thought of as a collection of 'multi-sets'. For example, $[3]^{(2)}$ consists of the sets

$$\emptyset, \{1\}, \{2\}, \{3\}, \{1,2\}, \{1,3\}, \{2,3\},$$

while $[3]^2$ consists of the multisets

$$\emptyset, \{1\}, \{1,1\}, \{2\}, \{2,2\}, \{3\}, \{3,3\}, \{1,2\}, \{1,3\}, \{2,3\}.$$

In general, $[n]^{(k)}$ consists of $\sum_{i=0}^{k} \binom{n}{i}$ sets, and $[n]^k$ consists of $\binom{n+k}{k}$ multisets. With a slight abuse of mathematical notation, $[n]^{(k)} \subseteq [n]^k$. For each $\emptyset \neq S \in [n]^k$, and for any $\mathbf{x} = (x_1, x_2, \ldots, x_n) \in \mathbf{R}^n$, $\mathbf{x}_S$ denotes the product of the x_i for $i \in S$ (with repetitions as required). For example, $\mathbf{x}_{\{1,2,3\}} = x_1 x_2 x_3$ and $\mathbf{x}_{\{1,1,2\}} = x_1^2 x_2$. We define $\mathbf{x}_\emptyset = 1$ for all $\mathbf{x}$.

It is clear that the basis functions ϕ_i for the PDFs may be written in the form $\phi_i(\mathbf{x}) = \mathbf{x}_S$ for some non-empty multi-set S. Therefore a function defined on $\mathbf{R}^n$ is a PDF of order at most k if and only if there are constants w_S, one for each $S \in [n]^k$, such that

$$f(\mathbf{x}) = \rho \left[\sum_{S \in [n]^k} w_S \mathbf{x}_S \right]. \tag{48}$$

Restricting attention to $\{0,1\}$ inputs, note that any term $\mathbf{x}_S$ in which S contains a repetition is redundant, simply because for $x = 0$ or 1, $x^r = x$ for all r; thus, for example, for binary inputs, $x_1 x_2^2 x_3^3 = x_1 x_2 x_3$. Therefore, we arrive at the following characterisation of $\mathcal{P}_{\mathbf{B}}(n,k)$. A function $f : \{0,1\}^n \to \{0,1\}$ is in $\mathcal{P}_{\mathbf{B}}(n,k)$ if and only if there are constants w_S, one for each $S \in [n]^{(k)}$, such that

$$f(\mathbf{x}) = \rho \left[\sum_{S \in [n]^{(k)}} w_S \mathbf{x}_S \right]. \tag{49}$$

Of course, each boolean PDF is the restriction to $\{0,1\}^n$ of a PDF; what we have emphasized here is that in the case when the inputs are restricted to be 0 or 1,

some redundancy can be eliminated immediately. This last observation shows that in considering the classes $\mathcal{P}_{\mathbf{B}}(n,k)$, it suffices to use extended vectors of the form

$$\tilde{\mathbf{x}}^T = [\ \psi_1(\mathbf{x}) \quad \psi_2(\mathbf{x}) \quad \cdots \quad \psi_m(\mathbf{x})\ ], \tag{50}$$

where each ψ_i is of the form

$$\psi_i(\mathbf{x}) = \mathbf{x}_S = \prod_{i \in S} x_i, \tag{51}$$

for a non-empty subset S of at most k elements of $[n]$. The number of such S, and hence the length of these extended vectors, is $\sum_{i=1}^{k} \binom{n}{i}$. For general PDFs of order at most k, one uses the extended vectors of equation 44, of length $\binom{n+k}{k} - 1$; the entries here are $\mathbf{x}_S$ for $\emptyset \neq S \in [n]^k$.

4.3 VC dimension and independence of basis functions

As noted earlier, classification by LWNNs corresponds to classification by linear threshold functions of the extended vectors in the corresponding higher-dimensional space. This is explicit in the context of PDFs and boolean PDFs from equations 48 and 49.

We shall make use of the following well-known characterisation of sets shattered by homogeneous linear threshold functions, a proof of which we include for completeness.

Lemma 15 *A subset $S = \{\mathbf{y}_1, \mathbf{y}_2, \ldots, \mathbf{y}_s\}$ of $\mathbf{R}^d$ can be shattered by the set of homogeneous linear threshold functions on $\mathbf{R}^d$ if and only if S is a linearly independent set of vectors.*

Proof: Suppose that the vectors are linearly dependent. Then at least one of the vectors is a linear combination of the others. Without loss, suppose that $\mathbf{y}_1 = \sum_{i=2}^{s} \lambda_i \mathbf{y}_i$ for some constants λ_i, $(2 \leq i \leq s)$. Let $\langle \mathbf{x}, \mathbf{y} \rangle$ denote the standard (Euclidean) inner product on $\mathbf{R}^d$. Suppose $\mathbf{w}$ is such that for $2 \leq j \leq s$, $\langle \mathbf{w}, \mathbf{y}_j \rangle > 0$ if and only if $\lambda_j > 0$. Then $\langle \mathbf{w}, \mathbf{y}_1 \rangle = \sum_{i=2}^{s} \lambda_i \langle \mathbf{w}, \mathbf{y}_j \rangle \geq 0$. It follows that there

is no homogeneous linear threshold function for which $\mathbf{y}_1$ is a negative example and, for $2 \leq j \leq s$, $\mathbf{y}_j$ is a positive example if and only if $\lambda_j > 0$. That is, the set S of vectors is not shattered.

For the converse, it suffices to prove the result when $s = d$. Let $\mathbf{A}$ be the matrix whose rows are the vectors $\mathbf{y}_1, \mathbf{y}_2, \ldots, \mathbf{y}_d$ and let $\mathbf{v}$ be any of the 2^d vectors with entries $1, -1$. Then $\mathbf{A}$ is nonsingular and so the matrix equation $\mathbf{A}\mathbf{w} = \mathbf{v}$ has a solution. The homogeneous linear threshold function t defined by this solution weight-vector $\mathbf{w}$ satisfies $t(\mathbf{y}_j) = 1$ if and only if entry j of $\mathbf{v}$ is 1. Thus all possible classifications of the set of vectors can be realised, and the set is shattered. □

Recall that a set $\{h_1, h_2, \ldots, h_s\}$ of functions defined on a set X is *linearly dependent* if there are constants λ_i $(1 \leq i \leq s)$, not all zero, such that, *for all* $\mathbf{x} \in X$,

$$\lambda_1 h_1(\mathbf{x}) + \lambda_2 h_2(\mathbf{x}) + \ldots + \lambda_s h_s(\mathbf{x}) = 0; \tag{52}$$

that is, if some non-trivial linear combination of the functions is the zero function on X. The following result is due to Dudley [13]; we present here a new proof based on the idea of extended vectors.

Theorem 16 *Let $\mathcal{H}$ be a vector space of real-valued functions defined on a set X. Suppose that $\mathcal{H}$ has (vector space) dimension d. For any $h \in \mathcal{H}$, define the $\{0,1\}$-valued function h_+ on X by*

$$h_+(\mathbf{x}) = \begin{cases} 1 & \text{if } h(\mathbf{x}) \geq 0 \\ 0 & \text{if } h(\mathbf{x}) < 0, \end{cases} \tag{53}$$

and define

$$\text{nonneg}(\mathcal{H}) = \{h_+ : h \in \mathcal{H}\}\,. \tag{54}$$

Then the VC dimension of $\text{nonneg}(\mathcal{H})$ *is d.*

Proof: Suppose that $\{h_1, h_2, \ldots, h_d\}$ is a basis for $\mathcal{H}$ and, for $\mathbf{x} \in X$, let $\mathbf{x}^{\mathcal{H}} = (h_1(\mathbf{x}), h_2(\mathbf{x}), \ldots, h_d(\mathbf{x}))$. The subset S of X is shattered by $\text{nonneg}(\mathcal{H})$ if and only if for each $S^+ \subseteq S$ there is $h \in \mathcal{H}$ such that $h(\mathbf{x}) \geq 0$ if $\mathbf{x} \in S^+$ and $h(\mathbf{x}) < 0$ if $\mathbf{x} \in S^- = S \setminus S^+$. But, since $\{h_1, \ldots, h_d\}$ is a basis of $\mathcal{H}$, for any $h \in H$ there

are constants w_i $(1 \leq i \leq d)$ such that $h = \sum_{i=1}^{d} w_i h_i$. Thus, equivalently, S is shattered by nonneg($\mathcal{H}$) if and only if there are constants w_i such that

$$\sum_{i=0}^{d} w_i h_i(\mathbf{x}) \begin{cases} \geq 0 & \text{if } \mathbf{x} \in S^+; \\ < 0 & \text{if } \mathbf{x} \in S^-; \end{cases} \tag{55}$$

that is, the inner product $\left\langle \mathbf{w}, \mathbf{x}^{\mathcal{H}} \right\rangle$ is non-negative for $\mathbf{x} \in S^+$ and is negative for $\mathbf{x} \in S^-$. But this says precisely that the linear threshold function t given by

$$t(\mathbf{x}) = \rho[w_1 x_1 + w_2 x_2 + \ldots w_d x_d] \tag{56}$$

satisfies

$$t(\mathbf{x}^{\mathcal{H}}) = \begin{cases} 1 & \text{if } \mathbf{x} \in S^+ \\ 0 & \text{if } \mathbf{x} \in S^-, \end{cases} \tag{57}$$

It follows that the set S is shattered if and only if the set $\{\mathbf{x}^{\mathcal{H}} \mid \mathbf{x} \in S\}$ is shattered by homogeneous linear threshold functions in $\mathbf{R}^d$. Hence, by lemma 15, $\mathcal{V}(\text{nonneg}(\mathcal{H})) \leq d$. Further, by lemma 15, the VC dimension equals d if and only if there is a set $\left\{\mathbf{x}_1^{\mathcal{H}}, \ldots, \mathbf{x}_d^{\mathcal{H}}\right\}$ of linearly independent extended vectors in $\mathbf{R}^d$. Suppose this is not so. Then the vector subspace of $\mathbf{R}^d$ spanned by the set $\left\{\mathbf{x}^{\mathcal{H}} \mid \mathbf{x} \in X\right\}$ is of dimension at most $d-1$ and therefore is contained in some hyperplane. Hence there are constants $\lambda_1, \lambda_2, \ldots, \lambda_d$, not all zero, such that for every $\mathbf{x} \in X$, $\sum_{i=1}^{d} \lambda_i (\mathbf{x}^{\mathcal{H}})_i = 0$. But this means that for all $\mathbf{x} \in X$, $\sum_{i=1}^{d} \lambda_i h_i(\mathbf{x}) = 0$, and hence the function $\sum_{i=1}^{d} \lambda_i h_i$ is identically zero on X, contradicting the linear independence of $h_1, \ldots, h_d$. It follows that the VC dimension of nonneg($\mathcal{H}$) is d, as claimed. □

This theorem is very useful and has been mentioned already in earlier parts of this paper. It applies directly to linearly weighted neural networks as follows.

Theorem 17 *Let $\Phi = \{\phi_1, \ldots, \phi_m\}$ be a given set of basis functions defined on a set X and let $\mathcal{F}_n^{\Phi}$ be the set of linearly weighted neural networks on X based on Φ. If $\{1, \Phi\}$ is a linearly independent set in the vector space of real-valued functions on X, where 1 denotes the identically-1 function on X, then $\mathcal{V}(\mathcal{F}_n^{\Phi}) = m + 1$. In general $\mathcal{V}(\mathcal{F}_n^{\Phi})$ is the maximum cardinality of a linearly independent subset of $\{1, \Phi\}$.*

Proof: Let $\mathrm{Sp}(1, \Phi)$ be the vector space of real functions on X spanned by the identically-1 function on X and the basis functions $\Phi = \{\phi_1, \phi_2, \ldots, \phi_m\}$. Then $\mathrm{Sp}(1, \Phi)$ consists of all functions of the form

$$h(\mathbf{x}) = w_0 + w_1\phi_1(\mathbf{x}) + \ldots + w_m\phi_m(\mathbf{x}) \tag{58}$$

for all possible choices of constants w_i. It is clear from this and equation 1 that

$$\mathcal{F}_n^{\Phi} = \mathrm{nonneg}(\mathrm{Sp}(1, \Phi)), \tag{59}$$

so that the VC dimension of $\mathcal{F}_n^{\Phi}$ is the vector-space dimension of $\mathrm{Sp}(1, \Phi)$. The result follows. □

4.4 VC dimension of PDFs

We now apply the above results to the classes $\mathcal{P}(n, k)$ and $\mathcal{P}_{\mathbf{B}}(n, k)$. For $\mathcal{P}(n, k)$, the full class of PDFs of order at most k, the basis functions are given by $\phi_i(\mathbf{x}) = \mathbf{x}_S$ for $\emptyset \neq S \in [n]^k$. For $\mathcal{P}_{\mathbf{B}}(n, k)$, the basis functions can be taken to be $\psi_i(\mathbf{x}) = \mathbf{x}_S$ where $\emptyset \neq S \in [n]^{(k)}$. Let

$$\Phi(n, k) = \left\{\mathbf{x}_S \mid \emptyset \neq S \in [n]^k\right\}, \quad \Phi_{\mathbf{B}}(n, k) = \left\{\mathbf{x}_S \mid \emptyset \neq S \in [n]^{(k)}\right\}. \tag{60}$$

Proposition 18 *For all n and k, the set $\{1, \Phi(n, k)\}$ is a linearly independent set of real functions on $\mathbf{R}^n$.*

Proof: We prove by induction on n that for all m, $\{1, \Phi(n, k)\}$ is a linearly independent set of real functions on $\mathbf{R}^n$. The base case $n = 1$ is straightforward; it is well-known that the functions $1, x, x^2, x^3, \ldots, x^m$ are linearly independent. (This can be verified analytically or by using Wronskians; see [25], for example.)

Suppose now that the assertion is true for a value of $n \geq 1$ and let k be any positive integer. By the inductive assumption, the set $\{\mathbf{x}_S : S \in [n]^k\}$ is a linearly independent set. For $0 \leq k \leq m$, let $M_r \subseteq [n+1]^k$ be the set of or multi-subsets containing $n+1$ exactly r times. Suppose that for some constants α_S, for all $\mathbf{x} \in \mathbf{R}^{n+1}$,

$$\sum_{S \in [n+1]^k} \alpha_S \mathbf{x}_S = 0. \tag{61}$$

Then,

$$\sum_{r=0}^{k} x_{n+1}^{r} \sum_{S \in S_r} \alpha_S \mathbf{x}_S^* = 0 \tag{62}$$

for all $\mathbf{x}$, where, for $S \in S_r$, $\mathbf{x}_S^*$ is $\mathbf{x}_S$ with the r factors equal to $\mathbf{x}_{n+1}$ deleted. (So, $\mathbf{x}_S^*$ is of the form $\mathbf{x}_T$ for some $T \in [n]^k$; that is, $\mathbf{x}_S^* \in \Phi(n,k)$.) It follows, from the linear independence of $1, \mathbf{x}_{n+1}, \mathbf{x}_{n+1}^2, \ldots, \mathbf{x}_{n+1}^m$, that for all $\mathbf{x}_1, \mathbf{x}_2, \ldots, \mathbf{x}_n$, we have

$$\sum_{S \in S_r} \alpha_S \mathbf{x}_S^* = 0 \tag{63}$$

for each r. But the inductive assumption then implies that for all r and for all $S \in S_r$, $\alpha_S = 0$; that is, all the coefficients α_S are zero. Hence the functions are linearly independent. □

Now consider $\Phi_{\mathbf{B}}(n,k)$, regarded as a set of real functions on domain $X = \{0,1\}^n$.

Proposition 19 *For all n, k with $k \leq n$, $\{1, \Phi_{\mathbf{B}}(n,k)\}$ is a linearly independent set of real functions defined on $\{0,1\}^n$.*

Proof: Let $n \geq 1$, and suppose that for some constants α_0 and α_S, for all $\mathbf{x} \in \{0,1\}^n$,

$$A(\mathbf{x}) = \alpha_0 + \sum_{\emptyset \neq S \in [n]^{(k)}} \alpha_S \mathbf{x}_S = 0. \tag{64}$$

Set $\mathbf{x}$ to be the all-0 vector to deduce that $\alpha_0 = 0$. Let $1 \leq r \leq k$ and assume, inductively, that $\alpha_S = 0$ for all $S \subseteq [n]$ with $|S| < r$. Let $S \subseteq [n]$ with $|S| = r$. Setting $x_i = 1$ if $i \in S$ and $x_j = 0$ if $j \notin S$, we deduce that $A(\mathbf{x}) = \alpha_S = 0$. Thus for all S of cardinality r, $\alpha_S = 0$. Hence $\alpha_S = 0$ for all S, and the functions are linearly independent. □

The above two results, coupled with theorem 17, enable us to determine the VC dimensions of the classes of PDFs and boolean PDFs.

Corollary 20 *For all n, k,*

$$\mathcal{V}(\mathcal{P}(n,k)) = \binom{n+k}{k}, \tag{65}$$

and for all n, k with $k \leq n$,

$$\mathcal{V}(\mathcal{P}_{\mathbf{B}}(n,k)) = \sum_{i=0}^{k} \binom{n}{i}. \tag{66}$$

Note that if all inputs are restricted to be binary and if $m > 1$, then the VC dimension of the corresponding LWNN is lower than if the inputs are allowed to be arbitrary real numbers. We remark that the VC dimensions coincide for $m = 1$, the case of linear threshold functions.

Theorem 17 tells us a little more than this. As mentioned near the beginning of this section, one may only be interested in LWNNs based on a strict subset of the basis functions $\Phi(n,k)$. For example, the special case of RBFNs in which the centres are fixed or variable and the function ϕ is of the form $\phi(r) = r^i$ for an even positive integer i, reduces essentially to PDFs based on some of the functions $\phi_i(\mathbf{x}) = \prod_{1 \leq i \leq n} x_i^{ri}$ as in equation 44. But since the set $\{1, \Phi(n,k)\}$ is a linearly independent set for any n, k, it follows that any LWNN based on a strict subset of m of the functions in $\cup_{k \geq 1} \Phi(n,k)$ has VC dimension $m+1$. A similar comment applies to binary-input LWNNs based on strict subsets of $\Phi_{\mathbf{B}}(n,k)$ for all n and for any $k \leq n$. These observations may be summarized as follows.

Theorem 21 *Any class of PDFs based on m of the standard basis functions $\cup_{k \geq 1} \Phi(n,k)$ has VC dimension $m+1$. Any class of boolean PDFs based on m of the standard boolean PDF basis functions $\Phi_{\mathbf{B}}(n,n)$ has VC dimension $m+1$.* □
